1 Introduction

Given the opportunity to review the design document and related smart contract source code of the Onyx DAO Registry contracts, we outline in the report our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of the smart contract is well-engineered without major security concerns. This document outlines our audit results.

1.1 About Onyx

Onyx Protocol is a blockchain that enables the streamlined issuance and management of digital assets via smart contracts. It is maintained by a federation of block signers and features a scalable UTXO model for efficient transaction validation. The protocol is governed by Onyx DAO through Onyxcoin (XCN), which allows token holders to vote on protocol updates. This audit covers the specific Onyx DAO Registry contract that maintains a number of provider metadata for the Onyx DAO. The basic information of audited contracts is as follows:

1.2 About PeckShield

PeckShield Inc. [5] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

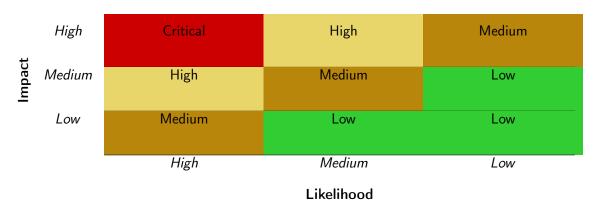

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on OWASP Risk Rating Methodology [4]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would

Table 1.3: The Full List of Check Items

Category	Check Item

	Making Type Inference Explicit		
	Adhering To Function Declaration Strictly		
	Following Other Best Practices		

additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- Basic Coding Bugs: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [3], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this security audit is not designed to replace functional tests required before any software release, and does not give any warranties on finding all possible security issues of the given smart contract(s) or blockchain software, i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary		
Configuration	Weaknesses in this category are typically introduced during		
	the configuration of the software.		
Data Processing Issues	Weaknesses in this category are typically found in functional-		
	ity that processes data.		
Numeric Errors	Weaknesses in this category are related to improper calcula-		
	tion or conversion of numbers.		
Security Features	Weaknesses in this category are concerned with topics like		
	authentication, access control, confidentiality, cryptography,		
	and privilege management. (Software security is not security		
	software.)		
Time and State	Weaknesses in this category are related to the improper man-		
	agement of time and state in an environment that supports		
	simultaneous or near-simultaneous computation by multiple		
Funcio Con d'Alons	systems, processes, or threads.		
Error Conditions,	Weaknesses in this category include weaknesses that occur if		
Return Values, Status Codes	a function does not generate the correct return/status code, or if the application does not handle all possible return/status		
Status Codes	codes that could be generated by a function.		
Resource Management	Weaknesses in this category are related to improper manage-		
Nesource Management	ment of system resources.		
Behavioral Issues	Weaknesses in this category are related to unexpected behav-		
Deliavioral issues	iors from code that an application uses.		
Business Logics	Weaknesses in this category identify some of the underlying		
Dusiness Togics	problems that commonly allow attackers to manipulate the		
	business logic of an application. Errors in business logic can		
	be devastating to an entire application.		
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used		
	for initialization and breakdown.		
Arguments and Parameters	Weaknesses in this category are related to improper use of		
_	arguments or parameters within function calls.		
Expression Issues	Weaknesses in this category are related to incorrectly written		
	expressions within code.		
Coding Practices	Weaknesses in this category are related to coding practices		
	that are deemed unsafe and increase the chances that an ex-		
	ploitable vulnerability will be present in the application. They		
	may not directly introduce a vulnerability, but indicate the		
	product has not been carefully developed or maintained.		

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the implementation of the Onyx DAO Registry contracts. During the first phase of our audit, we study the smart contract source code and run our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logic, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	0	
Medium	0	
Low	1	
Informational	0	
Total	1	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities that need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 1 low-severity vulnerability.

Table 2.1: Key Onyx DAO Registry Audit Findings

ID	Severity	Title	Category	Status
PVE-001	Low	Trust Issue Of Admin Keys	Security Features	Mitigated

Beside the identified issues, we emphasize that for any user-facing applications and services, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms should kick in at the very moment when the contracts are being deployed on mainnet. Please refer to Section 3 for details.

3 Detailed Results

3.1 Trust Issue Of Admin Keys

• ID: PVE-001

Severity: Low

• Likelihood: Low

• Impact: Low

• Impact: Medium

• Target: OnyxDAORegistry

• Category: Security Features [2]

• CWE subcategory: CWE-287 [1]

Description

In the audited <code>OnyxDAORegistry</code> contracts, there is a privileged account (<code>owner</code>) that plays a critical role in governing and regulating the contract-wide operations, namely, configuring a number of <code>DAO-wide</code> parameters. In the following, we show the representative functions potentially affected by the privilege of this account.

```
1159
          function setInfrastructureProvider(string calldata value) external onlyOwner {
1160
              emit ProviderUpdated("infrastructureProvider", infrastructureProvider, value);
1161
              infrastructureProvider = value;
1162
1163
1164
          function setHostingProvider(string calldata value) external onlyOwner {
1165
              emit ProviderUpdated("hostingProvider", hostingProvider, value);
1166
              hostingProvider = value;
1167
         }
1168
1169
         function setDAOManager(string calldata value) external onlyOwner {
1170
              emit ProviderUpdated("daoManager", daoManager, value);
1171
              daoManager = value;
1172
         }
1173
1174
          function setAIProvider(string calldata value) external onlyOwner {
1175
              emit ProviderUpdated("aiProvider", aiProvider, value);
1176
              aiProvider = value;
1177
          }
1178
1179
          function setSequencerProvider(string calldata value) external onlyOwner {
```

```
1180
              emit ProviderUpdated("sequencerProvider", sequencerProvider, value);
1181
              sequencerProvider = value;
1182
1183
1184
          function setWalletProvider(string calldata value) external onlyOwner {
1185
              emit ProviderUpdated("walletProvider", walletProvider, value);
1186
              walletProvider = value;
1187
         }
1188
1189
          function _authorizeUpgrade(address newImplementation) internal override onlyOwner {}
```

Listing 3.1: Example Privileged Operations in OnyxDAORegistry

In the meantime, the registry contract makes use of the proxy contract to allow for future upgrades. The upgrade is a privileged operation, which also falls in this trust issue on the admin key.

Recommendation Promptly transfer the privileged account to the intended DAO-like governance contract. All changed to privileged operations may need to be mediated with necessary timelocks. Eventually, activate the normal on-chain community-based governance life-cycle and ensure the intended trustless nature and high-quality distributed governance.

Status The issue has been confirmed and will be mitigated with the planned transfer to a timelock (so all writes/upgrades will pass through timelock delay).

4 Conclusion

In this audit, we have analyzed the design and implementation of the Onyx DAO Registry contracts in Onyx, which is a blockchain that enables the streamlined issuance and management of digital assets via smart contracts. It is maintained by a federation of block signers and features a scalable UTXO model for efficient transaction validation. The audited Onyx DAO Registry contract maintains a number of provider metadata for the Onyx DAO. The current code base is well structured and neatly organized. Those identified issues are promptly confirmed and addressed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.
